

Haskell 简介

张凯

2015 年 8 月 5 日

介绍

开胃菜

- pandoc – 文件格式转换的利器
 - 读入: Markdown, reStructuredText, LaTeX, DocBook, EPUB, Word docx 等等格式
 - 输出: DZSlides, reveal.js, beamer; HTML5, pdf, Word docx, LaTeX
- xmonad – 平铺式窗口管理器
 - 资源占用少
 - 基本功能一应俱全
 - 配置文件即 Haskell 程序, 定制灵活

Haskell 的优点

- 没有副作用 -> 易于查错, 测试
- 变量不可变 -> 易于执行并发操作
- 惰性求值 -> 提高效率, 表达无穷列表
- 静态类型 + 强大的类型推导系统 -> 节省代码量
- 尾递归优化 -> 代码更简洁

Haskell 的缺点

- 非主流 -> 目前主要在学术界流行, 工业界用的较少
- 执行效率不如 C、C++ 高
- 学习曲线陡峭

细节

基本语法

- `doubleUs x y = x*2 + y*2`
 - `doubleUs 4 9 -> 26`
- `list`
 - `:, ++, !!;`
 - `head, tail; last, init;`
 - `take, drop;`
 - `maximum, minimum; sum, product`
 - `elem, .., repeat`
 - `[x*2 | x <- [1..10], x*2 >= 12]`

基本语法 2

- `tuple`
 - `fst (8, 11)`
 - `snd`
 - `zip`

type

```
addThree :: Int -> Int -> Int -> Int
addThree x y z = x + y + z
```

- `curry`
 - `Int -> (Int -> (Int -> Int))`
 - `((addThree x) y) z`

Function

- Pattern matching

```
lucky :: (Integral a) => a -> String
lucky 7 = "LUCKY NUMBER SEVEN!"
lucky x = "Sorry, you're out of luck, pal!"
```

- Guards

```

bmiTell :: (RealFloat a) => a -> String
bmiTell bmi
  | bmi <= 18.5 = "You're underweight, you emo, you!"
  | bmi <= 25.0 = "You're supposedly normal. Pffft, I bet you're ugly!"
  | bmi <= 30.0 = "You're fat! Lose some weight, fatty!"
  | otherwise  = "You're a whale, congratulations!"

```

Function 2

- case

```

describeList :: [a] -> String
describeList xs =
  "The list is " ++ case xs of [] -> "empty."
                              [x] -> "a singleton."
                              xs -> "a longer list."

```

递归

```

quicksort :: (Ord a) => [a] -> [a]
quicksort [] = []
quicksort (x:xs) =
  let smallerSorted = quicksort [a | a <- xs, a <= x]
      biggerSorted = quicksort [a | a <- xs, a > x]
  in smallerSorted ++ [x] ++ biggerSorted

```

Map and filter

```

map :: (a -> b) -> [a] -> [b]
map _ [] = []
map f (x:xs) = f x : map f xs
filter :: (a -> Bool) -> [a] -> [a]
filter _ [] = []
filter p (x:xs)
  | p x      = x : filter p xs
  | otherwise = filter p xs

ghci> map (+3) [1,5,3,1,6]
[4,8,6,4,9]
ghci> filter (>3) [1,5,3,2,1,6,4,3,2,1]
[5,6,4]

```

Fold, (\$) and (.)

```
sum' :: (Num a) => [a] -> a
sum' xs = foldl (\acc x -> acc + x) 0 xs

map' :: (a -> b) -> [a] -> [b]
map' f xs = foldr (\x acc -> f x : acc) [] xs

($) :: (a -> b) -> a -> b
f $ x = f x

(.) :: (b -> c) -> (a -> b) -> a -> c
f . g = \x -> f (g x)
```

Modules

```
Geometry/
  |--Sphere.hs
  |--Cuboid.hs
  |--Cube.hs
```

Sphere.hs

```
module Geometry.Sphere
( volume
, area
) where

volume :: Float -> Float
volume radius = (4.0 / 3.0) * pi * (radius ^ 3)

area :: Float -> Float
area radius = 4 * pi * (radius ^ 2)
```

Define our type

```
data Car = Car { company :: String
                 , model  :: String
                 , year   :: Int
                 } deriving (Show)

ghci> Car {company="Ford", model="Mustang", year=1967}
Car {company = "Ford", model = "Mustang", year = 1967}
```

```
type String = [Char]

newtype CharList = CharList { getCharList :: [Char] }
    deriving (Eq, Show)
```

闭包

```
class Monoid m where
    mempty :: m
    mappend :: m -> m -> m
    mconcat :: [m] -> m
    mconcat = foldr mappend mempty
```

Monad

- 带 context 的类型
- 只要实现 `class Monad m`, 就不必关心 context 细节了, 只需考虑传递的变量
- Monad 实现了 Haskell pure 部分与非 pure 部分的隔离
